Tidal friction: The mutual attraction between the Moon and the material in the bulge tends to accelerate the Moon in its orbit, thereby moving the Moon farther from Earth by about three centimetres (1.2 inches) per year, and to slow Earth's daily rotation by a small fraction of a second per year.

Tidal forces stretch the Earth in the direction of the tide-producing body because of the inverse square law, i.e., the force on the near side is greater than the force on the far side, giving a net stretching force. While more noticeable in the oceans, there is also tidal stretching of the land masses.

The tidal bulges that occur thanks to the moon result in friction, friction that slows down the Earth's rotation. This is called tidal friction, the effect of a tidal wave slowing down the

Ocean Tides and the Earth's Rotation An Introductory Discussion Courtesy of the IERS Special Bureau for Tides. Tides affect the earth's rotation in two sharply contrasting

ways. One way, caused by tidal friction, produces an extremely slow secular change in rotation. The other way, caused by the continual movements of the tides about the planet, produces very small but very rapid changes in

In the four years which elapsed between our first workshop on Tidal Friction and the Earth's Rotation and the second, the proceedings of which are presented here, many of the disciplines involved made advances which we felt should be exchanged. We were encouraged by the good reception our first

Tidal acceleration - Wikipedia

Tidal acceleration is an effect of the tidal forces between an orbiting natural satellite (e.g. the Moon), and the primary planet that it orbits (e.g. Earth). The acceleration causes a gradual recession of a satellite in a prograde orbit away from the primary, and a corresponding slowdown of the primary's rotation.
